

MATRIX EXPONENTIALS AND INVERSION OF CONFLUENT VANDERMONDE MATRICES *

UWE LUTHER[†] AND KARLA ROST[‡]

Abstract. For a given matrix A we compute the matrix exponential e^{tA} under the assumption that the eigenvalues of A are known, but without determining the eigenvectors. The presented approach exploits the connection between matrix exponentials and confluent Vandermonde matrices V . This approach and the resulting methods are very simple and can be regarded as an alternative to the Jordan canonical form methods. The discussed inversion algorithms for V as well as the matrix representation of V^{-1} are of independent interest also in many other applications.

Key words. matrix exponential, Vandermonde matrix, fast algorithm, inverse.

1. Introduction. Given a (complex) matrix A of order n , the problem of evaluating its matrix exponential e^{tA} is important in many applications, e.g., in the fields of dynamical systems or control theory.

While the matrix exponential is often represented in terms of an infinite series or by means of the Jordan canonical form our considerations have been inspired by papers like [7] and [6], where alternative methods are discussed. In an elementary way we here develop a representation of e^{tA} which involves only the eigenvalues (but not the eigenvectors), the first $(n - 1)$ powers of A , and the inverse of a corresponding confluent Vandermonde matrix V . Such a representation was already given in [4], where an important motivation was to arrange the approach and the proofs simple enough to be taught to beginning students of ordinary differential equations. We here make some slight simplifications by proving such a representation, but we also concentrate our attention to the problem of developing fast recursive algorithms for the inversion of the confluent Vandermonde matrix V in the spirit of [4].

There is a large number of papers dealing with algorithms for nonconfluent and confluent Vandermonde matrices. They mainly utilize the well-known connection of Vandermonde systems with interpolation problems (see, e.g., [3] and the references therein). Moreover, in [10], [9] the displacement structure of V (called there the principle of UV-reduction) is used as a main tool.

In the present paper we want to stay within the framework of ordinary differential equations. Together with some elementary facts of linear algebra, we finally arrive at a first inversion algorithm which requires the computation of the partial fraction decomposition of $(\det(\lambda I - A))^{-1}$. This algorithm is in principle the algorithm developed in a different way in [11]. We here present a second algorithm which can be considered as an improvement of the first one since the preprocessing of the coefficients of the partial fraction decomposition is not needed. Both algorithms are fast, which means that the computational complexity is $O(n^2)$. As far as we know the second algorithm gives a new version for computing V^{-1} . For the sake of simplicity, let us here roughly explain the main steps of this algorithm for the nonconfluent case $V = (\lambda_i^{j-1})_{i,j=1}^n$:

1. Start with the vector $\mathbf{h}_{n-1} = (1, 1, \dots, 1)^T \in \mathbb{C}^n$ and do a simple recursion to get vectors $\mathbf{h}_{n-2}, \dots, \mathbf{h}_0$ and form the matrix $H = (\mathbf{h}_0 \mathbf{h}_1 \dots \mathbf{h}_{n-1})$.
2. Multiply the j th row of V with the j th row of H to obtain numbers q_j and form the diagonal matrix $Q = \text{diag}(q_j)_1^n$.
3. Multiply H from the left by the diagonal matrix $P = Q^{-1}$ to obtain V^{-T} .

In the confluent case the diagonal matrix P becomes a block-diagonal matrix with upper triangular Toeplitz blocks (t_{i-j}) , $t_\ell = 0$ for $\ell > 0$.

Moreover, we show how the inversion algorithms described above lead to a matrix representation of V^{-1} , the main factor of which is just V^T . The other factors are diagonal matrices, a triangular Hankel matrix (s_{i+j}) , $s_\ell = 0$ for $\ell > n$, and a block diagonal matrix with triangular Hankel blocks. For the nonconfluent case such a representation is well known (see [13] or, e.g., [10]) and is also a straightforward consequence of a formula proved in [5]. In [12] a generalization of the result [5] to the confluent case is presented, which leads directly to a formula for V^{-1} of the form just described. Generalizations of representations of this kind to other classes of matrices such as Cauchy-Vandermonde matrices or generalized Vandermonde matrices can be found in [2] and [8]. Fast inversion algorithms for Vandermonde-like matrices involving orthogonal polynomials are designed in [1].

The paper is organized as follows. In Section 2 we discuss the connection of e^{tA} with confluent Vandermonde matrices V and prove the corresponding representation of e^{tA} . Section 3 is dedicated to recursive inversion algorithms for V . A matrix representation of V^{-1} is presented in Section 4. Finally, in Section 5 we give some additional remarks concerning alternative possibilities for proving results of Section 3, modified representations of e^{tA} in terms of finitely many powers of A , and the determination of analytical functions of A .

2. Connection between matrix exponentials and confluent Vandermonde matrices.

Let A be a given $n \times n$ complex matrix and let

$$(2.1) \quad p(\lambda) = \det(\lambda I - A) = \lambda^n + a_{n-1}\lambda^{n-1} + \dots + a_1\lambda + a_0$$

be its characteristic polynomial, $\lambda_1, \lambda_2, \dots, \lambda_m$ its eigenvalues with the (algebraic) multiplicities $\nu_1, \nu_2, \dots, \nu_m$, $\sum_{i=1}^m \nu_i = n$. In other words, we associate the polynomial

$$(2.2) \quad p(\lambda) = (\lambda - \lambda_1)^{\nu_1} \dots (\lambda - \lambda_m)^{\nu_m}$$

with the pairs (λ_i, ν_i) ($i = 1, 2, \dots, m$). We are going to demonstrate in a very simple way that the computation of e^{tA} can be reduced to the inversion of a corresponding confluent Vandermonde matrix. The only fact we need is well known from a basic course on ordinary differential equations: Each component of the solution $\mathbf{x}(t) = e^{tA}\mathbf{v}$ of the initial value problem

$$(2.3) \quad \mathbf{x}' = A\mathbf{x}, \quad \mathbf{x}(0) = \mathbf{v}$$

is a linear combination of the functions

$$(2.4) \quad e^{\lambda_1 t}, t e^{\lambda_1 t}, \dots, t^{\nu_1-1} e^{\lambda_1 t}, \dots, e^{\lambda_m t}, t e^{\lambda_m t}, \dots, t^{\nu_m-1} e^{\lambda_m t}.$$

Note that these functions are just n fundamental solutions of the ordinary differential equation

$$(2.5) \quad y^{(n)}(t) + a_{n-1}y^{(n-1)}(t) + \dots + a_0 y(t) = 0,$$

the constant coefficients of which are given in (2.1). To be more precise, there is an $n \times n$ matrix C such that

$$(2.6) \quad \mathbf{x}(t) = C\mathbf{e}(t),$$

where

$$\mathbf{e}(t) = (e^{\lambda_1 t}, te^{\lambda_1 t}, \dots, t^{\nu_1-1} e^{\lambda_1 t}, \dots, e^{\lambda_m t}, te^{\lambda_m t}, \dots, t^{\nu_m-1} e^{\lambda_m t})^T.$$

Now we use $\mathbf{x}(t) = C\mathbf{e}(t)$ as an ansatz and determine the unknown matrix C by comparing the initial values $\mathbf{x}^{(k)}(0) = C\mathbf{e}^{(k)}(0)$ with the given initial values $\mathbf{x}^{(k)}(0) = A^k \mathbf{v}$, $k = 0, 1, \dots, n-1$:

$$(2.7) \quad C\mathbf{e}^{(k)}(0) = A^k \mathbf{v}, \quad k = 0, 1, \dots, n-1.$$

Considering the vectors $\mathbf{e}(0), \mathbf{e}'(0), \dots, \mathbf{e}^{(n-1)}(0)$ and $\mathbf{v}, A\mathbf{v}, \dots, A^{n-1}\mathbf{v}$ as columns of the matrices V and $A_{\mathbf{v}}$, respectively,

$$(2.8) \quad V = (\mathbf{e}(0) \ \mathbf{e}'(0) \ \dots \ \mathbf{e}^{(n-1)}(0)), \quad A_{\mathbf{v}} = (\mathbf{v} \ A\mathbf{v} \ \dots \ A^{n-1}\mathbf{v}),$$

the equalities (2.7) can be rewritten in matrix form

$$(2.9) \quad CV = A_{\mathbf{v}}.$$

We state that V has the structure of a confluent Vandermonde matrix,

$$(2.10) \quad V = \begin{pmatrix} V(\lambda_1, \nu_1) \\ V(\lambda_2, \nu_2) \\ \vdots \\ V(\lambda_m, \nu_m) \end{pmatrix},$$

where

$$V(\lambda, \nu) = \begin{pmatrix} 1 & \lambda & \lambda^2 & \lambda^3 & \dots & \lambda^{n-1} \\ 0 & 1 & 2\lambda & 3\lambda^2 & \dots & (n-1)\lambda^{n-2} \\ 0 & 0 & 2 & 6\lambda & \dots & (n-1)(n-2)\lambda^{n-3} \\ \vdots & & & \ddots & & \vdots \\ 0 & \dots & 0 & (\nu-1)! & \dots & (n-1) \cdot \dots \cdot (n-\nu+1)\lambda^{n-\nu} \end{pmatrix}.$$

It is easy to see that V is nonsingular and together with (2.6) and (2.9) we obtain the following.

LEMMA 2.1. *The solution $\mathbf{x}(t)$ of the initial value problem (2.3) is given by*

$$(2.11) \quad \mathbf{x}(t) = e^{tA} \mathbf{v} = A_{\mathbf{v}} V^{-1} \mathbf{e}(t),$$

where $V, A_{\mathbf{v}}$ are defined in (2.8).

Now, taking into account that $A_{\mathbf{v}} V^{-1} \mathbf{e}(t) = \sum_{i=0}^{n-1} y_i(t) A^i \mathbf{v}$, where

$$(2.12) \quad (y_i(t))_{i=0}^{n-1} = V^{-1} \mathbf{e}(t),$$

(2.11) leads to the following expression of e^{tA} .

THEOREM 2.2 ([4], (1.10) and (1.15)). *The matrix exponential e^{tA} can be represented as*

$$(2.13) \quad e^{tA} = y_0(t)I + y_1(t)A + \dots + y_{n-1}(t)A^{n-1},$$

where $y_i(t)$, $i = 0, 1, \dots, n-1$, are defined in (2.12).

Let us define the multiplication of a row vector (A_1, \dots, A_n) of matrices $A_i \in \mathbb{C}^{n \times n}$ and a column vector $\mathbf{v} = (v_1, \dots, v_n)^T$ of scalars $v_i \in \mathbb{C}$ by

$$(2.14) \quad (A_1, A_2, \dots, A_n) \mathbf{v} = v_1 A_1 + v_2 A_2 + \dots + v_n A_n.$$

Then (2.12), (2.13) can be rewritten in a more compact form,

$$(2.15) \quad e^{tA} = (I, A, A^2, \dots, A^{n-1}) \mathbf{y}(t), \quad \text{where } \mathbf{y}(t) = V^{-1} \mathbf{e}(t).$$

Representation (2.15) is already known (see [4] and the references therein). The proof given in [4] is nice and, as promised there, it can be appreciated by students in a course on ordinary differential equations. In this paper the known initial values of e^{tA} are compared with the initial values of the ansatz

$$(2.16) \quad e^{tA} = (C_1, C_2, \dots, C_n) \mathbf{f}(t),$$

where $\mathbf{f}(t)$ is an arbitrary vector of n fundamental solutions of (2.5) and C_i are $n \times n$ matrices. But this requires the application of a formal vector-matrix product defined for matrices A_i , $i = 1, \dots, n$, and U of order n as follows:

$$(2.17) \quad (A_1, \dots, A_n) U = ((A_1, \dots, A_n) \mathbf{u}_1, \dots, (A_1, \dots, A_n) \mathbf{u}_n),$$

where \mathbf{u}_i denotes the i th column of U .

Possibly, the derivation given above is more natural and easier to understand. In particular, the special choice $\mathbf{f}(t) = \mathbf{e}(t)$ is also a simplification and does not mean any loss of generality. Of course, instead of the vector $\mathbf{e}(t)$, one can use any other vector $\mathbf{f}(t)$ of n fundamental solutions of (2.5). But, denoting by $W_{\mathbf{f}}$ the Wronski matrix of \mathbf{f} , $W_{\mathbf{f}} = (\mathbf{f} \ \mathbf{f}' \ \dots \ \mathbf{f}^{(n-1)})$, the equality (2.11) is replaced by $e^{tA} \mathbf{v} = A_{\mathbf{v}} V_{\mathbf{f}}^{-1} \mathbf{f}(t)$, where $V_{\mathbf{f}} = W_{\mathbf{f}}(0)$. This leads to the same representation (2.15) of e^{tA} , since $V_{\mathbf{f}}^{-1} \mathbf{f}(t)$ does not depend on the choice of \mathbf{f} (compare the proof of Lemma 3.1).

REMARK 2.3. Denoting by $e_k(t)$ the k th component of $\mathbf{e}(t)$ and by \mathbf{v}_k the k th column of V^{-1} , then $V^{-1} \mathbf{e}(t) = \sum_{k=1}^n e_k(t) \mathbf{v}_k$, and we obtain, as a consequence of (2.15), $e^{tA} = (C_1, C_2, \dots, C_n) \mathbf{e}(t)$, where

$$(2.18) \quad C_k = (I, A, A^2, \dots, A^{n-1}) \mathbf{v}_k.$$

In the sense of (2.17) this can be written as

$$(2.19) \quad (C_1, C_2, \dots, C_n) = (I, A, A^2, \dots, A^{n-1}) V^{-1}.$$

Let us summarize: For an $n \times n$ matrix A having the eigenvalues λ_i with the algebraic multiplicities ν_i the matrix exponential e^{tA} is given by (2.15), where V^{-1} is the inverse of the confluent Vandermonde matrix corresponding to the pairs (λ_i, ν_i) , $i = 1, \dots, m$, $\sum \nu_i = n$.

The special structure of the matrix V can be used to compute its inverse V^{-1} in a much more efficient way than, e.g., Gaussian eliminations do. Thus we will proceed with designing inversion algorithms the computational complexity of which is $O(n^2)$. Such fast algorithms have been already presented and discussed in a large number of papers (see e.g. [3] and references therein).

On one hand, we want to develop here a new version of such an algorithm; on the other hand, we intend to follow the spirit of the authors of [4], namely to be simple enough for a presentation to students of an elementary course on ordinary differential equations. Thus, we will discuss inversion algorithms exploiting elementary results of Linear Algebra, but, as far as it is possible, all within the framework of ordinary differential equations. Consequently, numerical aspects and criteria such as, e.g., stability will be beyond the scope of this paper, but will be discussed in a forthcoming paper.

3. Recursive algorithms for the inversion of V . Hereafter, let \mathbf{e}_k be the k th unit vector and \mathbf{w}_{k-1}^T the k th row of V^{-1} , $\mathbf{w}_{k-1}^T = \mathbf{e}_k^T V^{-1}$. We start with developing a recursion for the rows \mathbf{w}_i^T ($i = n-2, \dots, 0$) of V^{-1} from its last row \mathbf{w}_{n-1}^T . As a basis we use the following fact.

LEMMA 3.1. *The vector $\mathbf{y}(t) = V^{-1}\mathbf{e}(t)$ is the solution of the initial value problem*

$$(3.1) \quad \begin{cases} \mathbf{y}' = B\mathbf{y}, \\ \mathbf{y}(0) = \mathbf{e}_1, \end{cases} \quad \text{where } B = \begin{pmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \cdots & 0 & -a_1 \\ & \ddots & & \vdots & \vdots \\ 0 & \cdots & 1 & 0 & -a_{n-2} \\ 0 & \cdots & 0 & 1 & -a_{n-1} \end{pmatrix}$$

and a_0, \dots, a_{n-1} are the coefficients of the characteristic polynomial (2.1).

Proof. The matrix B is just the companion matrix of $p(\lambda)$. Moreover, since $(\mathbf{e}_1 B \mathbf{e}_1 \dots B^{n-1} \mathbf{e}_1) = I_n$ we conclude from (2.11) that $e^{tB} \mathbf{e}_1 = V^{-1} \mathbf{e}(t) = \mathbf{y}(t)$, which completes the proof. \square

COROLLARY 3.2. *The components of $\mathbf{y}(t) = (y_k(t))_{k=0}^{n-1}$ can be recurrently determined from the last component $y_{n-1}(t)$:*

$$(3.2) \quad y_{k-1}(t) = y'_k(t) + a_k y_{n-1}(t), \quad k = n-1, \dots, 1.$$

(For $k = 0$ this is also true if we set $y_{-1} = 0$.)

Let us introduce the block-diagonal matrix

$$(3.3) \quad \tilde{J} = \text{diag}(\tilde{J}_1, \dots, \tilde{J}_m),$$

where $\tilde{J}_i = \lambda_i$ in case $\nu_i = 1$, otherwise

$$\tilde{J}_i = \begin{pmatrix} \lambda_i & 1 & & & & \\ & \lambda_i & 2 & & & \\ & & \lambda_i & 3 & & \\ & & & \ddots & \ddots & \\ & & & & \lambda_i & \nu_i - 1 \\ & & & & & \lambda_i \end{pmatrix}.$$

Then, taking into account that $y_k(t) = \mathbf{w}_k^T \mathbf{e}(t)$ and $\mathbf{e}'(t) = \tilde{J}^T \mathbf{e}(t)$, we obtain the following reformulation of (3.2).

LEMMA 3.3. *The rows $\mathbf{w}_0^T, \dots, \mathbf{w}_{n-1}^T$ of V^{-1} satisfy the recursion*

$$(3.4) \quad \mathbf{w}_{k-1} = \tilde{J} \mathbf{w}_k + a_k \mathbf{w}_{n-1}, \quad k = n-1, \dots, 0.$$

(For $k = 0$ set $\mathbf{w}_{-1} = \mathbf{0}$.)

Now we are left with the problem how to compute the last row \mathbf{w}_{n-1}^T of V^{-1} . To solve this we decompose $p(\lambda)^{-1}$ into partial fractions

$$(3.5) \quad \frac{1}{p(\lambda)} = \sum_{i=1}^m \sum_{j=1}^{\nu_i} \frac{p_{ij}}{(\lambda - \lambda_i)^j}.$$

THEOREM 3.4. *The last row \mathbf{w}_{n-1}^T of V^{-1} is given, by the coefficients of (3.5), as follows*

$$(3.6) \quad \mathbf{w}_{n-1}^T = \left(\frac{p_{11}}{0!}, \frac{p_{12}}{1!}, \dots, \frac{p_{1\nu_1}}{(\nu_1 - 1)!}, \dots, \frac{p_{m1}}{0!}, \dots, \frac{p_{m\nu_m}}{(\nu_m - 1)!} \right).$$

Proof. Since the function $\mathbf{y}(t) = (y_i(t))_{i=0}^{n-1}$ satisfies $\mathbf{y}^{(k)}(0) = B^k \mathbf{e}_1 = \mathbf{e}_{k+1}$ for $k = 0, 1, \dots, n-1$ (see Lemma 3.1) we obtain, in particular, that the last component $y_{n-1}(t) = \mathbf{w}_{n-1}^T \mathbf{e}(t)$ is the solution of the initial value problem

$$(3.7) \quad y^{(n)} + a_{n-1}y^{(n-1)} + \dots + a_0y = 0,$$

$$(3.8) \quad y(0) = \dots = y^{(n-2)}(0) = 0, \quad y^{(n-1)}(0) = 1.$$

We consider now the Laplace transform of $y_{n-1}(t)$ defined by

$$(\mathcal{L}y_{n-1})(s) = \int_0^\infty e^{-st} y_{n-1}(t) dt.$$

In view of (3.8), \mathcal{L} applied to (3.7) yields $(\mathcal{L}y_{n-1})(s) = p(s)^{-1}$ which can be decomposed into partial fractions as in (3.5). By applying the back transform we obtain

$$\begin{aligned} y_{n-1}(t) &= \sum_{i=1}^m \sum_{j=1}^{\nu_i} \frac{p_{ij}}{(j-1)!} t^{j-1} e^{\lambda_i t} \\ &= \left(\frac{p_{11}}{0!}, \frac{p_{12}}{1!}, \dots, \frac{p_{1\nu_1}}{(\nu_1-1)!}, \dots, \frac{p_{m1}}{0!}, \dots, \frac{p_{m\nu_m}}{(\nu_m-1)!} \right) \mathbf{e}(t), \end{aligned}$$

and (3.6) is proved. \square

Now we are in the position to propose a first inversion algorithm for V .

Algorithm I:

- 1) Compute the coefficients p_{ij} of the partial fraction expansion (3.5) and form the vector \mathbf{w}_{n-1} as in (3.6).
- 2) Compute the remaining rows of V^{-1} via the recursion (3.4).

It is well known that the coefficients in the partial fraction decomposition can be computed by means of an ansatz and the solution of a corresponding linear system of equations. This can be organized in such a way that the computational complexity of Algorithm I is $O(n^2)$.

We propose now a further possibility the advantages of which seem to be that the precomputing of the coefficients p_{ij} is not necessary and that the recursion starts always with a ‘‘convenient’’ vector. To that aim let us adopt some notational convention. Introduce the following block-diagonal matrices with upper triangular Toeplitz blocks,

$$\begin{aligned} P &= \text{diag}(P_k)_{k=1}^m \quad \text{with} \quad P_k = \begin{pmatrix} p_{k\nu_k} & p_{k\nu_k-1} & \cdots & p_{k1} \\ & p_{k\nu_k} & \ddots & \vdots \\ & & \ddots & p_{k\nu_k-1} \\ 0 & & & p_{k\nu_k} \end{pmatrix}, \\ J &= \text{diag}(J_k)_{k=1}^m \quad \text{with} \quad J_k = \begin{pmatrix} \lambda_k & 1 & & 0 \\ & \ddots & \ddots & \\ & & \lambda_k & 1 \\ 0 & & & \lambda_k \end{pmatrix} \in \mathbb{C}^{\nu_k \times \nu_k}, \end{aligned}$$

and define the diagonal matrix

$$D = \text{diag}(D_k)_{k=1}^m \quad \text{with} \quad D_k = \text{diag} \left(\frac{1}{0!}, \frac{1}{1!}, \dots, \frac{1}{(\nu_k-1)!} \right).$$

Obviously, D and P are nonsingular matrices.

It is easy to see that

$$(3.9) \quad \mathbf{w}_{n-1} = DP\mathbf{h}_{n-1},$$

where \mathbf{h}_{n-1} is the sum of the unit vectors $\mathbf{e}_{\nu_1}, \mathbf{e}_{\nu_1+\nu_2}, \dots, \mathbf{e}_n$, i.e.,

$$(3.10) \quad \mathbf{h}_{n-1} = \underbrace{(0, \dots, 0, 1, 0, \dots, 0, 1, \dots, 0, \dots, 0, 1)}_{\nu_1} \underbrace{, \dots, 0, 1, \dots, 0, 1, \dots, 0, \dots, 0, 1}_{\nu_2} \dots \underbrace{, \dots, 0, 1}_{\nu_m}.$$

We consider the recursion

$$(3.11) \quad \mathbf{h}_{k-1} = J\mathbf{h}_k + a_k\mathbf{h}_{n-1}, \quad k = n-1, \dots, 0.$$

LEMMA 3.5. *The recursion (3.11) produces the rows \mathbf{w}_{k-1}^T of V^{-1} as follows*

$$(3.12) \quad \mathbf{w}_{k-1} = DP\mathbf{h}_{k-1}, \quad k = n, \dots, 1.$$

(Putting $\mathbf{w}_{-1} = \mathbf{0}$ the equality (3.12) is also true for $k = 0$.)

Proof. We have, due to (3.11) and (3.9),

$$(3.13) \quad DP\mathbf{h}_{k-1} = DPJ\mathbf{h}_k + a_k\mathbf{w}_{n-1}, \quad k = n-1, \dots, 0.$$

Now, it is easy to verify that $\tilde{J}D = DJ$ and $JP = PJ$. Hence, (3.13) shows that

$$DP\mathbf{h}_{k-1} = \tilde{J}DP\mathbf{h}_k + a_k\mathbf{w}_{n-1}, \quad k = n-1, \dots, 0.$$

We compare this with (3.4) and state that $DP\mathbf{h}_{-1} = \mathbf{0}$ implies $\mathbf{h}_{-1} = \mathbf{0}$, which completes the proof. \square

The following fact has been already stated in [11].

COROLLARY 3.6. *The transpose of the matrix V^{-1} is given by $V^{-T} = DPH$, where $H = (\mathbf{h}_0 \mathbf{h}_1 \dots \mathbf{h}_{n-1})$.*

From Corollary 3.6 it follows that $P^{-1} = HV^TD$. On the other hand we have $P^{-1} = \text{diag}(Q_k)_{k=1}^m$ with $Q_k = P_k^{-1}$. One can easily see that the inverse of a (nonsingular) upper triangular Toeplitz matrix is again an upper triangular Toeplitz matrix, i.e., that Q_k has the form

$$(3.14) \quad Q_k = \begin{pmatrix} q_{k\nu_k} & q_{k\nu_k-1} & \cdots & q_{k1} \\ & q_{k\nu_k} & \ddots & \vdots \\ & & \ddots & q_{k\nu_k-1} \\ 0 & & & q_{k\nu_k} \end{pmatrix},$$

where $\mathbf{q}^{(k)} = (q_{k1}, \dots, q_{k\nu_k})^T$ is the last column of P_k^{-1} , i.e., the solution of the equation $P_k\mathbf{q}^{(k)} = \mathbf{e}_{\nu_k}$. Thus, the matrix $Q = P^{-1}$ is completely given by that n elements of $HV^T = QD^{-1}$ which stand in the last columns of the diagonal blocks of HV^T ,

$$(3.15) \quad HV^T = \text{diag}(Q_k D_k^{-1})_{k=1}^m.$$

With the entries of the vector $\mathbf{q}^{(k)}$ we form the matrix Q_k and compute the solution $\mathbf{p}^{(k)} = (p_{k1}, \dots, p_{k\nu_k})^T$ of

$$(3.16) \quad Q_k\mathbf{p}^{(k)} = \mathbf{e}_{\nu_k},$$

which gives the matrix P_k .

Now we propose the following second inversion algorithm for V .

Algorithm II:

- 1) Compute recurrently the columns \mathbf{h}_{j-1} , $j = 1, \dots, n$ of H by (3.11).
- 2) Compute that n elements $q_{kj}(\nu_k - 1)!$ of the product HV^T (see (3.15)) which determine the blocks Q_k (see (3.14)) of the matrix $P^{-1} = \text{diag}(Q_k)_{k=1}^m$.
- 3) Compute the upper triangular Toeplitz matrices P_k by solving (3.16) and form the matrix $P = \text{diag}(P_k)_{k=1}^m$.
- 4) Compute $V^{-1} = (DPH)^T$.

In the case that the multiplicities ν_k are small compared with n the computational complexity of the algorithm is again $O(n^2)$.

Our next aim is to develop the matrix representation of V^{-1} . A nice algebraic proof was given in [12]. The only motivation for us to add a second proof is to be more self-contained within the framework of ordinary differential equations.

4. Matrix representation of V^{-1} . Let us start with the *nonconfluent case*. Since in this case $\tilde{J} = \text{diag}(\lambda_i)_1^n$, the recursion (3.4) together with (3.6) leads directly to the representation

$$V^{-1} = U(\mathbf{a}) V^T \text{diag}(p_{k1})_{k=1}^n, \quad \text{where } U(\mathbf{a}) = \begin{pmatrix} a_1 & \cdots & a_{n-1} & 1 \\ \vdots & \ddots & \ddots & \\ a_{n-1} & 1 & & \\ 1 & & & 0 \end{pmatrix}.$$

(Note that $p_{k1} = p'(\lambda_k)^{-1}$.) This means that the inverse of a Vandermonde matrix V is closely related to its transpose V^T .

Such a representation is also possible in the *confluent case*. Recall that $p(\lambda) = \sum_{i=0}^n a_i \lambda^i$, where $a_n = 1$. Then the matrix H can be computed as follows.

LEMMA 4.1.

$$(4.1) \quad H = \sum_{i=0}^{n-1} J^i \mathbf{h}_{n-1}(a_{i+1}, \dots, a_n, 0, \dots, 0).$$

This lemma is a consequence of the observation that the columns of the right hand side of (4.1) satisfy the recursion (3.11).

Let Z_{ν_k} be the $\nu_k \times \nu_k$ counteridentity matrix defined as having ones on the antidiagonal and zeros elsewhere. Obviously, $P_k Z_{\nu_k}$ are upper upper triangular Hankel matrices of order ν_k . We obtain the following matrix representation of V^{-1} .

THEOREM 4.2.

$$(4.2) \quad V^{-1} = U(\mathbf{a}) V^T \text{diag}(G_k)_{k=1}^m,$$

where $G_k = D_k P_k Z_{\nu_k} D_k$.

Proof. From the obvious equality $P_k Z_{\nu_k} = Z_{\nu_k} P_k^T$ it follows

$$\text{diag}(G_k)_{k=1}^m = DZP^T D, \quad \text{where } Z = \text{diag}(Z_{\nu_k})_{k=1}^m.$$

Furthermore, $U(\mathbf{a}) = \sum_{i=0}^{n-1} \mathbf{e}_{i+1} \mathbf{a}^{(i)}$, where $\mathbf{a}^{(i)} = (a_{i+1}, \dots, a_n, 0, \dots, 0)$. Consequently, (4.2) is equivalent to $V^{-T} = DPZDV \sum_{i=0}^{n-1} \mathbf{e}_{i+1} \mathbf{a}^{(i)}$. In view of Corollary 3.6 and Lemma 4.1 it remains to show that

$$(4.3) \quad \sum_{i=0}^{n-1} J^i \mathbf{h}_{n-1} \mathbf{a}^{(i)} = ZDV \sum_{i=0}^{n-1} \mathbf{e}_{i+1} \mathbf{a}^{(i)}.$$

For this end we apply the formula for e^{tJ} which is well known from the theory of ordinary differential equations. This formula yields

$$(4.4) \quad e^{tJ} \mathbf{h}_{n-1} = ZD \mathbf{e}(t).$$

If we compare (4.4) with $e^{tJ} \mathbf{h}_{n-1} = (\mathbf{h}_{n-1} J \mathbf{h}_{n-1} \cdots J^{n-1} \mathbf{h}_{n-1}) V^{-1} \mathbf{e}(t)$ (Lemma 2.1), then we obtain $(\mathbf{h}_{n-1} J \mathbf{h}_{n-1} \cdots J^{n-1} \mathbf{h}_{n-1}) = ZDV$ and (4.3) is proved. \square

5. Final remarks.

REMARK 5.1. The assertion $\mathbf{w}_{k-1} - \tilde{J}\mathbf{w}_k = a_k\mathbf{w}_{n-1}$ ($k = 0, \dots, n-1$) of Lemma 3.3, written in matrix form $V^{-T}S_n - \tilde{J}V^{-T} = \mathbf{w}_{n-1}(a_0, a_1, \dots, a_{n-1})$, where S_n is the forward shift of order n , is the so-called displacement equation for V^{-T} (see [9]). This equation can also be deduced from the well known equality $B^T V^T = V^T \tilde{J}$, where B is defined in (3.1).

REMARK 5.2. To prove the assertion of Theorem 3.4 one can use, instead of the Laplace transformation, the Laurent series expansion at infinity of $(\lambda - \lambda_i)^{-j}$ (see [2]).

REMARK 5.3. In Section 2 we have only used that each component of e^{tA} is a solution of (2.5). This fact is a consequence of the Cayley-Hamilton theorem $p(A) = 0$. Hence, if $q(\lambda) = \lambda^N + b_{N-1}\lambda^{N-1} + \dots + b_1\lambda + b_0$ is any other polynomial with $q(A) = 0$, for example the minimal polynomial of A , then the components of e^{tA} are solutions of $y^{(N)}(t) + b_{N-1}y^{(N-1)}(t) + \dots + b_0y(t) = 0$ (since the matrix valued function $Y(t) = e^{tA}$ solves this equation). So we obtain, in the same way as in Section 2, $e^{tA}\mathbf{v} = (\mathbf{v} A \mathbf{v} A^2 \mathbf{v} \dots A^{N-1} \mathbf{v}) V_q^{-1} \mathbf{e}_q(t)$, where V_q is the confluent Vandermonde matrix corresponding to the zeros of $q(\lambda)$ and $\mathbf{e}_q(t)$ denotes the vector of the standard fundamental solutions of the above differential equation of order N . The resulting representation of e^{tA} is $e^{tA} = (I, A, A^2, \dots, A^{N-1}) \mathbf{y}_q(t)$, where $\mathbf{y}_q(t) = V_q^{-1} \mathbf{e}_q(t)$.

REMARK 5.4. Assume for sake of simplicity that all ν_k are equal to ν , where ν is small compared with n . Then using representation (4.2) the matrix-vector multiplication with the inverse of a (confluent) Vandermonde matrix V can be done with $O(n \log^2 n)$ computational complexity. Indeed, utilizing FFT techniques then the complexity of the multiplication of an $n \times n$ triangular Hankel matrix and a vector is $O(n \log n)$. In particular, this leads to a complexity of $O(n)$ for the matrix vector multiplication with $\text{diag}(G_k)_{k=1}^m$. Now, the rows of the matrix V^T can be reordered in such a way that the first m rows form a nonconfluent $m \times n$ Vandermonde matrix, the $(km+1)$ th up to $((k+1)m)$ th rows a nonconfluent Vandermonde matrix multiplied by a diagonal matrix, $k = 1, \dots, \nu$. With the ideas of [2] concerning the nonconfluent case this leads to a complexity of $O(n \log^2 n)$ to multiply V^T with a vector.

REMARK 5.5. From Lemma 3.1 one obtains a nice formula for the exponential of the companion matrix B , $e^{tB} = (\mathbf{y}(t) \mathbf{y}'(t) \dots \mathbf{y}^{(n-1)}(t))$. If A is nonderogatory, i.e., if there exists a nonsingular matrix U such that $AU = UB$, then we obtain the representation $e^{tA} = A_{\mathbf{v}} (\mathbf{y}(t) \mathbf{y}'(t) \dots \mathbf{y}^{(n-1)}(t)) A_{\mathbf{v}}^{-1}$, where $\mathbf{v} = U\mathbf{e}_1$ (which implies $A_{\mathbf{v}} = U$). We remark that A is nonderogatory if and only if there exists a \mathbf{v} such that $A_{\mathbf{v}}$ is invertible. This follows from $A_{\mathbf{v}}B = AA_{\mathbf{v}}$ which can be easily proved.

REMARK 5.6. For $f(z) = e^z$ we have $f(A) = (I, A, \dots, A^{n-1}) \cdot f(B)\mathbf{e}_1$ (since $\mathbf{y}(t) = e^{tB}\mathbf{e}_1$). This is also true for other power series $f(z) = \sum_{m=0}^{\infty} \alpha_m(z - z_0)^m$ with convergence radius $R > 0$ and its corresponding matrix valued function $f(A)$ ($A \in \mathbb{C}^{n \times n}$ with $\max_i |\lambda_i(A) - z_0| < R$). Indeed, if we compare the initial values of both sides of the equation $e^{-z_0 t} e^{tA} = (I, A, \dots, A^{n-1}) \cdot e^{-z_0 t} e^{tB} \mathbf{e}_1$, then we obtain $(A - z_0 I)^m = (I, A, \dots, A^{n-1}) \cdot (B - z_0 I)^m \mathbf{e}_1$ which yields the assertion. For the application to an vector this means $f(A)\mathbf{v} = A_{\mathbf{v}}\mathbf{b}$, where $\mathbf{b} = f(B)\mathbf{e}_1$. We remark that \mathbf{b} is just the coefficient vector of the Hermite interpolation polynomial of $f(z)$ with respect to the eigenvalues λ_i of A and their algebraic multiplicities ν_i . This follows from the well known equality $VBV^{-1} = \tilde{J}^T$: $V\mathbf{b} = Vf(B)V^{-1}V\mathbf{e}_1 = f(\tilde{J}^T)V\mathbf{e}_1 = (f(\lambda_1), f'(\lambda_1), \dots, f^{(\nu_1-1)}(\lambda_1), \dots, f(\lambda_m), \dots, f^{(\nu_m-1)}(\lambda_m))^T$.
